PEINWEEK.

The Referral Loop: A Guide for Frontline Clinicians on Electromyography and Nerve Conduction Studies

Ramon L. Cuevas-Trisan, MD

Title & Affiliation

Ramon L. Cuevas-Trisan, MD Associate Chief of Staff for Education & Research VA Medical Center West Palm Beach, FL

Disclosures

No financial relationship to disclose

I work for the Department of Veterans Affairs and my presentation does not represent the views of the VA or the US Federal Government

Learning Objectives

Describe the basic techniques used in electrodiagnostic testing in order to educate patients about these tests when referred
Formulate indications for electrodiagnostic studies in painful syndromes
Summarize the limitations of electrodiagnostic studies in painful syndromes

What are electrodiagnostic studies?

 Physiologic studies of the lower motor and sensory neuron unit (nerve roots, plexus, peripheral nerves and muscles)

- Used to determine if there are any problems along this "pathway"
- Type of problem, where is it, its extent, and its chronicity

Dillingham T, et. Al. Ch. 8 in Braddom's. Physical Medicine & Rehabilitation 5th Ed 2015

Who perform these?

- Generally Physiatrists and Neurologists
- Also technicians and others
- Know your people; these tests are highly operator-dependent

Why do we do these?

- "Objective" diagnostic tool / Mostly quantitative
- Like any diagnostic tool, should be utilized when results will affect treatment
- Serve to guide treatment and provide prognosis

Equipment

... that was then

Equipment

... this is now

- EMG Machine screen, computer, pre-amplifier
- Stimulator
- Surface recording electrodes
- Needle electrodes

Parts of a Study

- 2 separate but equally important parts; <u>separate or</u> <u>combined</u>
 - -Nerve Conduction Studies (NCS)
 - -Electromyography (EMG)

- Nerve stimulated at a point along its pathway depolarization evokes an action potential that travels along the nerve and is recorded by electrodes at a specific distance along that nerve's territory (skin or muscle)
- Stimulation by application of electrical current (1-100 mA)

No needles

Information obtained

- Latency time from delivery of the stimulus to the resulting recordable potential; mostly a function of integrity of the nerve's faster fibers myelin sheath
- <u>Amplitude</u> displacement of the action potential (in mV or μV) from the baseline; mostly a function of the number & integrity axons

Conduction velocity

A Few Trace Examples

F-wave <ulnar>

 Results are compared to pre-determined normal general population values; also compared (whenever possible) to the patient's own value (i.e. side-to-side/other comparable nerves)

Absolute and relative differences or deviations are noted

- Involves no electrical stimulation
- Recording of muscle-generated electrical potentials (voluntary and spontaneous) via a needle electrode inserted into the muscle tissue

Basic concepts of EMG

Needle electrodes – many types but general concept: teflon coated (electrically isolated) except at tip with a very small area of recording
Typical length – 25, 37, 50, 75 mm / 27G

Basic concepts of EMG

- Study will typically consist of evaluation of several muscles; from 1 to 10-15
- Muscles need to be observed fully relaxed/at rest; then patient asked to voluntarily activate/contract the muscle and signals analyzed
- Only assesses LMN anterior horn cell, nerves, and muscle; nothing sensory

Peripheral Neuropathies

- Diagnosis and characterization (demyelinating, axonal, mixed, motor, sensory)
- Most common: DM, EtOH, CRI, Hypothyroidism
- Others: toxic exposures heavy metals, antineoplastics (vincristine)
- HIV, Vit B-12 deficiency
- Hereditary
- AIDP, CIDP

Fateh, et al. J Diab Metab Dis 2016; 15:8

Dillingham T, et. al. Ch. 8 in Braddom's. Physical Medicine & Rehabilitation 5th Ed 2015

Painweek.

Focal neuropathies (CTS, Ulnar, TTS)
Plexopathies

Some Cranial Neuropathies (i.e. 7th)

Radiculopathies

motor only by EMG

 ideally - abnormalities in several muscles supplied by the same spinal nerve but different peripheral nerves/branches

Callaghan B. JAMA 2016; 315(3):297-298

Motor Neuron Disorders (i.e. ALS, PPS)₁ Myopathies (inflammatory vs. non-inflammatory)₂

I. Morris. Neurodiagnostic J 2015; 3:180-194

2. Carvalho. Clin Neurophysiol 2016; 127(7): 2670-81

Painweek.

Image: Image: Ima

Miscellaneous:

- neurogenic causes of anal sphincter dysfunction
- laryngeal EMG for dysphonia/VC paralysis
- dysfunction of the diaphragm

Geiger. Electrodiagnosis of NMJ Disorders 2018; 131-152

Most sensitive means of diagnosis
May not be as straightforward to diagnose clinically
Key before surgery
May co-exist with PN, worsening prognosis

Thompson Lancet 2017; 16(4): 263 Bland Orthopedics 2017; 40(4): 198-199 Masson J Clin Rheum 2016; 22(1): 45-46

Radiculopathy

Usually in combination with clinical exam/hx and imagingPhysiologic (functional) test vs. anatomic

Shoulder dysfunction scenario

High velocity blunt trauma to shoulder with shoulder subluxation
 MRI - full thickness supraspinatus and infraspinatus tendon tear
 Repair considered but on exam there are discrete areas of numbress in the arm

Focal vs Radicular, etc.

Unilateral leg pain, weakness (foot drop) and numbress
L5 vs. peroneal palsy ???

Some Pitfalls

Results are generally very useful but not always black and white
Hence the importance of using it as an extension of the H&P, like other diagnostic tests (i.e. labs, imaging)

More Pitfalls to bear in mind...

Radiculopathies

Pure Sensory >> Mixed >> Pure motor

For sensory we can use special NCS techniques called late responses; H-Reflex for S1 and C6-7; abnormalities are not pathognomonic but may support dx
 Also SSEP's¹

I. Eisen A. Can J Neurol Sci 1983; 10:178-182

More Pitfalls

Peripheral Neuropathies

- Will not detect small fiber neuropathies; better for compression than toxic/ischemic
- Painful small fiber neuropathies may be present and elude detection

Callaghan B. JAMA 2016; 315(3):297-298

Contraindications

NCS – demand-type pacemakers; particularly when stimulating nearby
 EMG – coagulopathies, anticoagulation, infected/wound site

Always evaluate benefit vs. risk ratio

Generally uncomfortable but tolerable; sedation never used

Proper Utilization

Longstanding diabetics with clear clinical PN for r/o diabetic neuropathy; may refer if other problems are suspected or superimposed

Proper Utilization

 Patients with pain complaints without objective neurological findings or at least anatomically-sound/concordant symptoms

Yield is usually too low

Proper Utilization

Pure UMN syndromes (i.e. SCI, Stroke)

• UMN is affected and in most cases the LMN is intact

Almost done....

How to Prepare/Counsel Patients

Wear loose comfortable clothing
No body creams or lotions
May or may not involve needles
Usually minimally painful, well-tolerated
Usually harmless / no expected complications
Go well-hydrated, no need to fast or to hold medications*

Timeframes

- sooner is not always better.....
- some abnormalities may not be seen immediately but may become apparent in days, weeks, or months

Timeframes

Study is dynamic at that point in time

 Having a clinical diagnosis dictates the basic protocol to follow; findings along the way prompt variations and modifications as the study progresses

Robinson L. Muscle Nerve 2015; 52:321-333

Timeframes

- Results from EMG cannot be reviewed later; analysis should happen in real time; to some extent true also for NCS
- Results are available immediately the study is being interpreted as it is being done

Other Concepts

- Rarely an emergency
- Possible exception: case of suspected AIDP when dx is needed to implement therapy – i.e. plasmapheresis

Dillingham T, et. Al. Ch. 8 in Braddom's. Physical Medicine & Rehabilitation 5th Ed 2015
